## ABSTRACT

The existence of Fe(II) and Fe(III) complexed CDOM has important ramifications for the speciation of iron in atmospheric waters. The Fe(III)-CDOM complex is a precursor to Fe(II) photochemical production where a ligand to metal charge transfer (LMCT) leads to the production of the reduced iron. Fe(II) and Fe(III) were added to Wilmington, NC rainwater containing chromophoric dissolved organic matter (CDOM). In general Fe(II) enhanced the fluorescence of CDOM while Fe(III) quenched CDOM fluorescence. The observation of fluorescence changes indicates complexation.

In authentic rain where Fe(II) and CDOM fluorescence were measured before and after irradiation there was a significant correlation between the photoproduction of Fe(II) and increased fluorescence. While in synthetic rainwater containing CDOM extracted from rainwater and added Fe(III) irradiation for 2 hours photoproduced Fe(II). The amount of Fe(II) produced was accurately predicted using a model calculation generated for predicting changes of Fe(II) in authentic rainwater using starting Fe(II), Fe(III), and  $H^+$  concentrations. The accuracy of this equation in both authentic and synthetic rainwater with added rainwater CDOM demonstrates the importance of CDOM for Fe(II) photoproduction. Once irradiation ceased Fe(II) oxidized slower in synthetic rainwater containing CDOM relative to synthetic rainwater without CDOM with a rate constant of  $1.66 \text{ nM h}^{-1}$  which is similar to authentic rainwater oxidation studies where the rate of oxidation range for was  $0.9 - 7 \text{ nM h}^{-1}$ . After 22 hours the remaining Fe(II) was protected against further oxidation by complexation with the extracted CDOM. The reproducibility between authentic rainwater and synthetic rain with added CDOM indicates that the ligand responsible for protecting Fe from oxidation is CDOM.

A solution of CDOM extracted from rain with added Fe(II) remained stable in a synthetic rainwater solution for 24 hours similar to observation in authentic rainwater; however very different from synthetic rainwater without CDOM. A solution of CDOM with Fe(II) had constant Fe(II) concentrations when mixed 1:1 with seawater for at least four hours, however Fe(II) in synthetic rain with no added CDOM became undetectable within three minutes of mixing with seawater. This stability of Fe(II) with added rain CDOM suggests that CDOM is the organic ligand responsible for protected Fe(II) from oxidation and its soluble form in natural waters.

## ACKNOWLEDGEMENTS

I would like to thank Dr. Robert Kieber, Dr. Joan Willey, and Dr Robert Whitehead for their constant guidance, support, and encouragement in completing this thesis. I send a special thank you to Leslie Bradshaw and Grant Pace for their friendship and amazing support though the many hard times both in the lab and out of the lab. I offer a blessing and namaste to the many yogis and yoginis that gave me strength and wisdom along the way. And finally with all my heart and love to Janice, my sister, Elaine, my beautiful grandmother, and Mike and Debbie Resetar, my parents, for their encouragement and goal orientation “Goal #1 Graduate!” We made it!

## LIST OF TABLES

Table	Page
1. Seasonal volume weighted averages from surface volume values. Total integration for initial rain events and the difference of integration by addition of Fe(II) is indicated. Samples were collected at Wilmington, NC between May, 3 2004 and July 14, 2005. Integration values are all relative to the polygon integration program designed by Coble (1996), n = number of samples.....	15
2. Trajectory volume weighted averages from surface volume. Trajectory category is divided up as according to Figure 5. Total integration for initial rain events and the difference of integration by addition of Fe(II) is indicated. Samples were collected at Wilmington, NC between May, 3 2004 and July 14, 2005. Integration values are all relative to the polygon integration program designed by Coble (1996).....	19
3. Trajectory volume weighted averages from surface volume values where trajectory categories are divided up as according to Figure 5. Total integration for initial rain events and the difference of integration by addition of Fe(III) is indicated. Samples were collected at Wilmington, NC between January 14, 2005 and May 17, 2005 .....	25
4. Physical parameters (pH, H <sub>2</sub> O <sub>2</sub> , and salinity) of reconcentrated CDOM in a 1:1 mixture of SRW and Gulf Coast seawater before and after mixing for e570 and after reconcentration mixing e589 .....	42

## LIST OF FIGURES

Figures	Page
1. Typical EEM spectra of rainwater. The A, M, C, and T labels are based upon the work of Coble (1996): where A and C indicate terrestrial humic-like substances, M is marine humic-like material and T indicates the presence of protein-like substances.....	10
2. Photochemical redox reaction of Fe(II) and Fe(III) with CDOM.....	11
3. Total fluorescence of EEM spectra of rain events with and without the addition of 250nM Fe(II). Error bars represent $\pm 1$ standard deviation ( $n = 3$ ). Samples were collected between May 3, 2004 and July 14, 2005. H.B. = Horse shoe Bay of the Cape Fear River 1:50 dilution .....	12
4. Total integrated fluorescence of synthetic rain in 1 $\mu$ M Ferrozine with the addition of 250 nM Fe(II) and Fe(III)/Fe (II) mix where the error bars indicate the standard deviation of 3 replicates.....	14
5. Plots of air mass back-trajectories calculated from the HYSPLIT model grouped by trajectory classification .....	17
6. Total integration fluorescence of EEM spectra of rain events with and without the addition of 250nM Fe(III). Samples were collected between January 14, 2005 and July 14, 2005. H.B. = Horse shoe Bay of the Cape Fear River 1:50 dilution; e = event of rain.....	21
7. Linear relationship between ambient rainwater fluorescence and $\Delta$ fluorescence (Fe(III) fluorescence – initial fluorescence) $n = 6$ , $r^2 = 0.9723$ , and $p < 0.001$ . The samples at (25013.8, 2526.8) represents the summer event 573.....	23
8. Normalized fluorescence ( $\Delta$ fluorescence/initial fluorescence) vs. date of sample collection, where the blue represents samples collected between January 14, 2005 to April 8, 2005 and the pink represent samples collected from April 14, 2005 to May 17, 2005 .....	24
9. Authentic rain events (e496, e501, e521, e533, e555, e559) that were irradiated for 6 hours. $\Delta$ Fe(II) L – D and $\Delta$ Total Fluorescence L – D represent the difference between the initial and final Fe(II) concentration and total fluorescence in light exposed and dark controls.....	27
10. Comparison of actual Fe(II) photoproduction in rainwater vs. predicted Fe(II) (nM) using equation 1 where $\Delta$ Fe(II) is the initial - final: $n = 6$ , $r^2 = 0.7537$ , and $p < 0.02$ .....	29

11. Rain event 521 was spiked with increasing amounts of Fe(II) (0-500 nM) prior to exposure to solar simulation. Iron(II) and total fluorescence concentration were measured initially then exposed to solar simulation for 6 hours. $\Delta$ Fe(II) L – D and $\Delta$ Total Fluorescence L – D represent the difference between the initial and final Fe(II) concentration and total fluorescence in light exposed and dark controls, n = 5, $r^2 = 0.919$ , p , 0.01.....	30
12. Comparison of actual Fe(II) photoproduced in rain event 521 versus the predicted Fe(II) (nM) when aliquots were spiked with Fe(II) 0 - 500 nM, the only point showing a loss of Fe(II) was the authentic event with no added Fe(II) all other aliquots showed photoproduction of Fe(II) where $\Delta$ Fe(II) is L-D: n = 5, $r^2 = 0.8753$ , and p < 0.01 .....	32
13. Concentration of Fe(II) (nM) as a function of time (hrs)in a rain sample (event 432) irradiated for 2 h (from time = 0 to time = 2 h) under simulated sunlight and then stored dark for the remainder of the experiment (from time = 2 to time = 26 h). Error bars represent $\pm 1$ standard deviation (n = 3) and are usually smaller then the symbol (Kieber et al. 2005) .....	33
14. Concentration of Fe(II) (nM) as a function of time (h) in SRW with added CDOM from (a) event 571 and (b) event 575, irradiated for 2 h (from time = 0 to time = 2 h) under solar simulation and then stored in the dark for the remainder of the experiment (from time = 2 to time = 24 h).....	34
15. Photoproduced Fe(II) by irradiation for 2 hours of SRW with added CDOM showing both actual $\Delta$ Fe(II) and predicted $\Delta$ Fe(II) concentrations by equation 1 based on initial Fe(II), Fe(III) concentration and pH.....	36
16. Concentration of Fe(II) (nM) as a function of time (min) in 150 mL SRW in the presence of CDOM extracted from 500 mL (a) event 570 (b) event 581. Error bars represent $\pm 1$ standard deviation based on n = 3.....	38
17. Concentration of Fe(II) (nM) as a function of time (min) in SRW brought back. Error bars represent $\pm 1$ standard deviation based on n = 3 and are usually smaller than the symbols .....	39
18. Concentration of Fe(II) (nM) as a function of time (h) in a 1:1 mixture of SRW and Gulf Coast sea water in the presence of extracted CDOM from (a) event 570 with pH = 8.20, $H_2O_2 = 10.70 \mu M$ , salinity = 15, and initial Fe(II) = 7.91 nM (b) event 589 with pH = 8.23, $H_2O_2 = 9.67 \mu M$ , salinity = 15, and initial Fe(II) = 19.05 nM.....	41
